# Data mining <br> Frequent itemsets <br> Association\&decision rule mining 

University of Szeged

## What frequent itemsets could be used for?

- Features/observations frequently co-occurring in some database can gain us useful insights
- How a marketing person can make use of it? What about a data scientist?

| Transaction ID | Items |
| :---: | :---: |
| 1 | \{milk, bread, salami\} |
| 2 | \{beer, diapers $\}$ |
| 3 | \{beer, wurst $\}$ |
| 4 | $\{$ beer, baby food, diapers $\}$ |
| 5 | \{diapers, coke, bread \} |

## Possible forms - Horizontal

| Transaction ID | Items |
| :---: | :---: |
| 1 | \{milk, bread, salami\} |
| 2 | \{beer, diapers $\}$ |
| 3 | \{beer, wurst $\}$ |
| 4 | $\{$ beer, baby food, diapers $\}$ |
| 5 | \{diapers, coke, bread $\}$ |

## Possible forms - Vertical/inverted

| Item | Basket |
| :---: | :---: |
| milk | $\{1\}$ |
| bread | $\{1,5\}$ |
| salami | $\{1\}$ |
| beer | $\{2,3,4\}$ |
| diapers | $\{2,4,5\}$ |
| wurst | $\{3\}$ |
| baby food | $\{4\}$ |
| coke | $\{5\}$ |

## Possible forms - Relational

| Basket | Item |
| :---: | :---: |
| 1 | milk |
| 1 | bread |
| 1 | salami |
| 2 | beer |
| 2 | diapers |
| 3 | beer |
| 3 | wurst |
| 4 | beer |
| 4 | baby food |
| 4 | diapers |
| 5 | diapers |
| 5 | coke |
| 5 | bread |

## Collecting association rules

- Goal: find item sets of the transactional database with high support and confidence
- Support of set $X: s(X)=\left|\left\{t_{i} \mid t_{i} \in T \wedge X \subseteq t_{i}\right\}\right|$
- Normalized support: $s(X)$ normalized by the number of transactions
- Confidence of rule $A \rightarrow B: c(A \rightarrow B)=\frac{s(A \cup B)}{s(A)} \approx P(B \mid A)$
- The meaning of a rule $A \rightarrow B$ : given that items included in set $A$ are put in the basket, chances are high that the items included in $B$ are also in some basket

## Interestingness of association rules

- Are all rules with high support and confidence equally interesting?
- Confidence of a rule can simply be high due to the fact the items on its right side are frequently purchased independently of the items on the left side. Any example?
- Interest score of rule $A \rightarrow B: I(A \rightarrow B)=c(A \rightarrow B)-P(B)$
- What is the interpretation of this score? (Interesting rules will have high absolute values. Why?)
- Choose threshold so that the number of rules defined is manageable
- There are plenty other scores for measuring interestingness: $\chi^{2}, \kappa, \ldots$

## What frequent itemsets can be utilized for? - Plagiarism detection

- Somewhat counter-intuitively let the sentences be the baskets and documents the items
- Conclusion
- Sometimes we need to be flexible about the concept of ,items" comprising „baskets"
- Our goal is to examine the relation of items to each other, and not that of baskets (we had that one before)
- How frequent itemsets could be interpreted if items and baskets were determined vice versa?

## What else frequent itemsets could be used for? - Data mining

- We can use them to build a simple classifier
- Missing feature values can be estimated knowing how features typically co-occur with each other
- We can merge features if they show highly similar behavior in the database

## The general schema of producing associational rules

- Collect the set of frequent items $F$ having a (normalized) support surpassing some threshold $t$
- Partition $F$ into non-empty, disjunct subsets and calculate the confidence of the rules determined

## Why naive approach fails?

- How a naive approach would look like?
- $d$ items $\Rightarrow 3^{d}-2^{d+1}+1$ possible rules (e.g. $d=9 \Rightarrow 18660$ possibilities)
- Proof (hint: $\left.(1+x)^{d}=\sum_{j=1}^{d}\binom{d}{j} x^{d-j}+x^{d}\right)$
- $\sum_{i=1}^{d}\binom{d}{i} \sum_{j=1}^{d-i}\binom{d-i}{j}=\sum_{i=1}^{d}\binom{d}{i}\left(2^{d-i}-1\right)=\sum_{i=1}^{d}\binom{d}{i} 2^{d-i}-\sum_{i=1}^{d}\binom{d}{i}=$
$\left(3^{d}-2^{d}\right)-\left(2^{d}-1\right)$

## A priori principle

- Itemset $I$ is frequent $\Rightarrow \forall J \subseteq I$ itemsets are frequent
- What can we say if itemset $I$ is not frequent?
- Anti-monotone property: function $f$ is said to be anti-monotone if $\forall X, Y \in \mathcal{P}(U): X \subseteq Y \Rightarrow f(X) \geq f(Y)$

## The A priori principle in action

- Let assume a frequency threshold of 3

| Item | Frequency |
| :---: | :---: |
| beer | 3 |
| bread | 4 |
| coke | 2 |
| diapers | 4 |
| milk | 4 |
| wurst | 1 |

## The A priori principle in action

- Let the frequency threshold be 3

| Item | Frequency |  |
| :---: | :---: | :---: |
| beer <br> bread | 3 |  |
| coke | 2 |  |
| diapers | 4 |  |
| milk | 4 |  |
| wurst | 1 |  |
| Item | Frequency |  |
| \{beer, bread\} | 2 |  |
| \{beer, diapers | 3 |  |
| \{beer, milk\} | 2 |  |
| \{bread, diapers | 3 |  |
| \{bread, milk | 3 |  |
| \{diapers, milk | 3 |  |

## Calculating frequent itemsets

1. Algorithm Pseudocode for calculation of frequent itemsets

Input: set of possible items U, transaction database T, frequency threshold t
Output: frequent itemsets
1: $C_{1}:=\mathcal{U}$
2: Calculate the support of $C_{1}$
3: $F_{1}:=\left\{x \mid x \in C_{1} \wedge s(x) \geq t\right\}$
4: for $\left(k=2 ; k<|\mathcal{U}| \& \& F_{k-1} \neq \emptyset ; k++\right)$ do
5: $\quad$ Determine $C_{k}$ based on $F_{k-1}$
6: Calculate the support of $C_{k}$
7: $\quad F_{k}:=\left\{X \mid X \in C_{k} \wedge s(X) \geq t\right\}$
8: end for
9: return $\cup_{i=1}^{k} F_{i}$

## Possible ways of determining $C_{k}$

- Based on the elements in $F_{1}$. Avoid this!
- Combining the elements of $F_{k-1}$ and $F_{1}$. Somewhat better
- Combining the elements of $F_{k-1}$ and $F_{k-1}$ itself. Generates less candidates but does not miss any candidate which has the chance to be a frequent itemset. Combine two itemsets if $\exists A=\left\{a_{1}, a_{2}, \ldots, a_{k-1}\right\}, B=\left\{b_{1}, b_{2}, \ldots, b_{k-1}\right\} \in F_{k-1}$ : $\forall a_{i}=b_{i}, 1 \leq i \leq k-2 \wedge a_{k-1} \neq b_{k-1}$
- We need an ordering over the elements of $F$ (e.g. by converting them to integers) and store them in that form

## Possible ways of calculating the frequency for $C_{k}$

- $\binom{\left|F_{k-1}\right|}{2}$ frequencies might need to be stored $\rightarrow$ memory limitations (for brevity, let $f=\left|F_{k-1}\right|$ )
- Depending on the ratio of non-zero elements, we can either store them proactively or store them reactively, in the form of ( $i, j, c$ ) triplets, storing by $c$ the co-occurrence of items $i$ and $j$
- In a one-dimensional triangular matrix, the frequency of item pair $(i, j), i<j$ is stored at index $(j-i)+\sum_{r=f-i+1}^{f-1} r \Rightarrow$ no need to explicitly store index values $i$ and $j$ for each counter
- If the number of zero frequencies surpasses $\frac{\binom{f}{2}}{3}$ representation using triplets pays off $(i, j, c)$

## Calculating $C_{k}$ - example

- Suppose there are $10^{7}$ baskets, 10 items/baskets
- There are $10^{5}$ different items in total
- Using the triangular matrix representation $\approx 5 * 10^{9}$ integer is required
- In worst case there are at most $10^{7}\binom{10}{2}$ different pairs of items in the transaction dataset $\rightarrow \max . \approx 3 * 4.5 * 10^{8}=1.35 * 10^{9}$ integer suffices to store the non.zero frequencies of the purchase of item pairs

## Compressing frequent itemsets

- Maximal frequent itemsets: $\{I \mid I$ frequent $\wedge \nexists$ frequent $J \supset I\}$
- Closed itemsets: $\{I \| J \supset I: s(J)=s(I)\}$
- Closed frequent itemsets: closed itemset having a support above some frequency threshold
- Can a maximal frequent itemset be non-closed?
- Can a closed itemset be non-maximal?

## Compressing frequent itemsets - Example ( $\mathrm{t}=3$ )

| Item | Frequency | Maximal | Closed | Closed frequent |
| :---: | :---: | :---: | :---: | :---: |
| A | 4 |  |  |  |
| B | 5 |  |  |  |
| C | 3 |  |  |  |
| AB | 4 |  |  |  |
| AC | 2 |  |  |  |
| BC | 3 |  |  |  |
| ABC | 2 |  |  |  |

## Compressing frequent itemsets - Example ( $\mathrm{t}=3$ )

| Item | Frequency | Maximal | Closed | Closed frequent |
| :---: | :---: | :---: | :---: | :---: |
| A | 4 | - | - | - |
| B | 5 | - | + | + |
| C | 3 | - | - | - |
| AB | 4 | + | + | + |
| AC | 2 | - | - | - |
| BC | 3 | + | + | + |
| ABC | 2 | - | + | - |

## The relation of different classes to each other

## Frequent itemsets

Closed frequent itemsets

Maximal frequent
itemsets

## PCY (Park-Chen-Yu) algorithm - an extension to A priori

- Besides counting the frequency of standalone items keep track of the frequency of buckets into which pairs of elements get assigned according to some hash function
- What can be said based on the aggregated frequency counts? What cannot be made for sure?
- Only pairs that consist of frequent items and which got hashed to a frequent bucket have the chance to be indeed frequent in the end

## Practical considerations

- We might as well do sampling from the transaction database $\Rightarrow$ correctness and completeness is sacrificed
- Different strategies can be applied for extracting frequent itemsets

## Generalizing A priori

- It is not necessary to do the expansion according to the different 'levels' of the item lattice
- We can do expansion according to any equivalent classes
- Originally we defined equivalent classes based on the size of the itemsets
- Alternatively we can define equivalent classes based on the size of the overlap in the prefixes/suffixes

## Generalizing A priori - the prefix and suffix view

(a) Prefix tree
(b) Suffix tree

## FP trees

- Use a data structure which makes the extraction of frequent datasets easy
- FP trees: alternative, condensed representation
- It can be constructed by processing the rows of the transaction database in one pass
- Market baskets are represented as paths in the tree
- Certain item subsets show up multiple times $\Rightarrow$ overlapping paths $\Rightarrow$ compressability
- Hopefully the whole transaction dataset can be stored in the main memory as a result

## Constructing FP trees

- Useful heuristic: order items according to their decreasing support
- Processing one line of the transaction database
- Continue paths starting from the root with the same prefix to the currently processed line
- Increment the frequencies stored for visited nodes
- Set the frequency of the new nodes to 1
- Otherwise start a new path from the root node
- Assign 1 for the frequency value of new nodes
- Include pointers between items of the same kind

## FP tree - example

[^0]
## FP tree - after processing the last basket

| TID | Items |
| :---: | :---: |
| 1 | $\{\mathrm{~A}, \mathrm{~B}\}$ |
| 2 | $\{\mathrm{~B}, \mathrm{C}, \mathrm{D}\}$ |
| 3 | $\{\mathrm{~A}, \mathrm{C}, \mathrm{D}, \mathrm{E}\}$ |
| 4 | $\{\mathrm{~A}, \mathrm{D}, \mathrm{E}\}$ |
| 5 | $\{\mathrm{~A}, \mathrm{~B}, \mathrm{C}\}$ |
| 6 | $\{\mathrm{~A}, \mathrm{~B}, \mathrm{C}, \mathrm{D}\}$ |
| 7 | $\{\mathrm{~B}, \mathrm{C}\}$ |
| 8 | $\{\mathrm{~A}, \mathrm{~B}, \mathrm{C}\}$ |
| 9 | $\{\mathrm{~A}, \mathrm{~B}, \mathrm{D}\}$ |
| 10 | $\{\mathrm{~B}, \mathrm{C}, \mathrm{E}\}$ |

- What trees would we get if items within baskets were ordered according to their increasing/decreasing order of overall support? (\{A:7,B:8,C:7,D:5,E:3\})

## Why to order items based on their support?

- Item $i$ that is ordered at position $r(i)$ among all the items, can add at most $2^{r(i)-1}$ nodes to an FP tree
- Another natural upper bound for the nodes of item $i$ in an FP tree is $s(i)$, hence it has $\leq \min \left(2^{r(i)-1}, s(i)\right)$ presences

| $i$ | A | B | C | D | E | $\Sigma$ |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $s(i)$ | 7 | 8 | 7 | 5 | 3 | 30 |
| $r_{1}(i)$ | 2 | 1 | 3 | 4 | 5 | - |
| presences | $\leq 2$ | 1 | $\leq 4$ | $\leq 5$ | $\leq 3$ | $\leq 15$ |
| $r_{2}(i)$ | 4 | 5 | 3 | 2 | 1 | - |
| presences | $\leq 7$ | $\leq 8$ | $\leq 4$ | $\leq 2$ | 1 | $\leq 22$ |

## FP-Growth algorithm

- Divide and conquer algorithm working on the FP tree in a bottom-up manner
- If the FP tree reveals that an itemset is frequent, check the support of its supersets
- Examine FP trees conditioned on some already known frequent itemsets
- E.g. as $\{E\}$ is frequent, check out the frequency of sets $\{A, E\}$, $\{B, E\},\{C, E\}$ and $\{D, E\}$

## FP trees conditioned on some target item(s)

- The part of the FP trees that we would get if we looked at only transactions containing the target item(s)
- Without building the tree from scratch
(1) Forget about the parts of the tree not related to the target item(s)

| TID | Basket |
| :---: | :---: |
| 1 | $\{A, B\}$ |
| 2 | $\{B, C, D\}$ |
| 3 | $\{A, C, D, E\}$ |
| 4 | $\{A, D, E\}$ |
| 5 | $\{A, B, C\}$ |
| 6 | $\{A, B, C, D\}$ |
| 7 | $\{B, C\}$ |
| 8 | $\{A, B, C\}$ |
| 9 | $\{A, B, D\}$ |
| 10 | $\{B, C, E\}$ |

FP tree conditioned on $\{E\}$

## FP trees conditioned on some target item(s)

- The part of the FP trees that we would get if we looked at only transactions containing the target item(s)
- Without building the tree from scratch
(2) Let the support of a node be the sum of the upgraded supports of its descendants

| TID | Basket |
| :---: | :---: |
| $\vdots$ | $\vdots$ |
| 3 | $\{A, C, D, E\}$ |
| 4 | $\{A, D, E\}$ |
| $\vdots$ | $\vdots$ |
| 10 | $\{B, C, E\}$ |

FP tree conditioned on $\{E\}$

## FP trees conditioned on some target item(s)

- The part of the FP trees that we would get if we looked at only transactions containing the target item(s)
- Without building the tree from scratch
(3) Eliminate items below frequency threshold (e.g. using a frequency threshold of 2)
(4) Create FP trees conditioned on item pairs (containing item $\{E\}$ ), based on which we can determine frequent item triples (e.g. $\{D, E\} \rightarrow\{A, D, E\}$ )

| TID | Basket |
| :---: | :---: |
| $\vdots$ | $\vdots$ |
| 3 | $\{A, C, D, E\}$ |
| 4 | $\{A, D, E\}$ |
| $\vdots$ | $\vdots$ |
| 10 | $\{B, C, E\}$ |

FP tree conditioned on $\{E\}$
